

Patient Information: *ANKRD26* gene

Why have I been given this information sheet?

You have been given this information sheet because you had genetic testing. This tested a sample of your blood cancer. Your cancer sample has shown an alteration in a gene called *ANKRD26*. This information sheet will help you understand what this means.

This gene alteration may partly explain why you have blood cancer. It may be used to help guide your treatment plan. The *ANKRD26* gene alteration may only be present in your cancer cells. It is also possible that it is a gene alteration you were born with. In this case, there may be an inherited cause for your cancer. You have the option of further tests to try to clarify this. If you are found to have an inherited gene alteration you will be referred to your local Clinical Genetics service. They will help you understand what this means for you and your family.

How often is blood cancer hereditary?

Most blood cancers do not have an inherited cause. Occasionally, blood cancer is linked to family history. Even if there is only one person in the family with blood cancer, it can sometimes still have an inherited cause.

We know of some gene alterations linked to an increased risk of blood cancer. Different words are used to describe these. These include “mutation,” “disease-causing alteration”, or “pathogenic variant.” The most up to date scientific term is “pathogenic variant.” This describes a gene alteration that is linked to an increased health risk.

What are the risks associated with inherited pathogenic variants in *ANKRD26*?

People who inherit a pathogenic variant in *ANKRD26* have an increased risk of thrombocytopenia (low platelet count). People with this condition can bleed easily. They can also take longer to stop bleeding. They should avoid medicines that can affect bleeding. It can also make some procedures more risky, for example surgery and labour in pregnancy. Sometimes people with this condition are severely affected. They are managed by a specialist team to help reduce bleeding risks.

People who inherit a pathogenic variant in *ANKRD26* have an increased risk of bone marrow problems and blood cancers. Not everyone with an inherited *ANKRD26* pathogenic variant develops cancer. We are still learning about this gene. We are not able to tell people their exact risks yet. The risks linked to this gene are not the same in all families. Over time, we will learn more about this.

Information for family members when an *ANKRD26* pathogenic variant is hereditary

We have two copies of the *ANKRD26* gene. The children of someone with an *ANKRD26* pathogenic variant have a 50% (1 in 2) chance of inheriting it. This is shown in the diagram below.

If your relatives are worried, they can ask for advice from their local genetics service. Testing is usually offered to close relatives first. This means parents, siblings and children. Testing is then offered to the wider family once we know which side it has come from, or which relatives are at risk.

What can you do about risks linked to an inherited *ANKRD26* pathogenic variant?

People at risk of bleeding problems will have a referral to a specialist. It will be to a specialist doctor called a haematologist. This is available on the NHS. They can tell you about medications and activities that are safe. People at risk can also register with the UK Haemophilia Centre. This provides specialist advice and healthcare.

People at risk may be offered a blood test to look for blood problems early. This test is limited in what it can find. People at an increased risk will be given the chance to talk through the pros and cons of this test.

It is important know what symptoms to look out for. The signs of a blood cancer are often non-specific. They include tiredness, weight loss and fever. They also include and excess bruising and bleeding. It is important to tell your GP about your genetic test result when you report any symptoms. Everyone can reduce their cancer risk by having a healthy diet and weight. Not smoking and drinking less alcohol also help.

Genetic testing in family members

Having a predictive genetic test for the inherited *ANKRD26* variant found in your family is a personal choice. . There is no routine monitoring that can detect blood cancer early in people with an *ANKRD26* variant. Not everyone wants to know about their cancer risk. The first step to genetic testing is a referral to a local genetics service. A GP can make this referral. A genetics appointment can be used to talk it through. After discussion people can make their own choice. Genetic testing may be used to help find out if a relative could be a match as a bone marrow donor.

Insurance

In the UK, there is a Code on Genetic Testing and Insurance. Insurance companies can only ask for the results of a predictive genetic test in limited circumstances. More information is on the Association of British Insurers website: <https://www.abi.org.uk/>. If you are taking out insurance, we suggest using an accredited insurance broker. This is important for life, critical illness, or income protection. Carefully read the small print when taking out insurance.

Resources and support

Having a genetic test can sometimes increase anxiety. If you have concerns, you can talk to your healthcare team. If you have already been referred to the Clinical Genetics service, you can contact your genetics doctor or genetic counsellor.

Information, practical & emotional support for families affected by any type of leukaemia, Myelodysplastic Syndrome (MDS) or Myelodysplastic Neoplasm (MPN)
